# Data Type

Most of the computer programming language support data type, variables, operator and expression like fundamentals. Python also support these.

# Data Types

Data Type specifies which type of value a variable can store. type() function is used to determine a variable's type in Python.

### **Mutable and Immutable Data type**

A mutable data type can change its state or contents and immutable data type cannot.

### Mutable data type:

list, dict, set

### Immutable data type:

int, float, complex, string, tuple, frozen set [note: immutable version of set, bytes

### 1. Number In Python

It is used to store numeric values

Python has three numeric types:

- 1. Integers
- 2. Floating point numbers
- 3. Complex numbers.

### 1. Integers

Integers or intarepositive or negative numbers with no decimal point. Integers in Python 3 are of unlimited size.

```
a= 100
b= -100
c= 1*20
print(a)
print(b)
print(c)
```

e.g.

```
Output :-
100
-100
200
```

### Type Conversion of Integer

int() function converts any data type to integer. e.g.

```
a = "101" # string
b=int(a) # converts string data type to integer.
c=int(122.4) # converts float data type to integer.
print(b)
print(c)
Output :-
101
122
```

## 2. Floating point numbers

It is a positive or negative real numbers with a decimal point.

e.g.

```
a = 101.2
b = -101.4
c = 111.23
d = 2.3*3
print(a) print(b) print(c)
print(d)
```

```
Output :- 101.2
-101.4
111.23
6.899999999999999
```

### **Type Conversion of Floating point numbers**

float() function converts any data type to floating point number.

```
e.g.
```

```
a='301.4' #string
b=float(a) #converts string data type to floating point number.
c=float(121) #converts integer data type to floating point number.
print(b)
print(c)Run Code
```

Output :- 301.4 121.0

### 3. Complex numbers

Complex numbers are combination of a real and imaginary part. Complex numbers are in the form of X+Yj, where X is a real part and Y is imaginary part.

```
e.g.
```

```
a = complex(5) # convert 5 to a real part val and zero imaginary part print(a)
b=complex(101,23) #convert 101 with real part and 23 as imaginary part print(b)
```

```
Output :- (5+0j) (101+23j)
```

### 2. String In Python

A string is a sequence of characters. In python we can create string using single (' ') or double quotes (" ").Both are same in python.

#### e.g.

```
str='computer science'
print('str-', str) # print string
print('str[0]-', str[0]) # print first char 'h'
print('str[1:3]-', str[1:3]) # print string from postion 1 to 3
'ell' print('str[3:]-', str[3:]) # print string staring from 3rd char 'llo
world' print('str *2-', str *2) # print string two times
print("str +'yes'-", str +'yes') # concatenated string
```

```
Output
str- computer science
str[0]- c
str[1:3]- om
str[3:]- puter science
str *2- computer sciencecomputer science
str +'yes'- computer scienceyes
```

### **Iterating through string**

```
e.g.
str='comp sc'
for i in str:
print(i)
```

### Output

C

0

m

p

S

C

### 3. Boolean In Python

It is used to store two possible values either true or false

```
e.g.
```

str="comp sc"
boo=str.isupper() # test if string contains upper case
print(boo)

Output False

### 4. List In Python

List are collections of items and each item has its own index value.

### 5. Tuple In Python

List and tuple, objects mean you cannot modify the contents of a tuple once it is assigneboth are same except, a list is mutable python objects and tuple is immutable Python objects. Immutable Python d.

```
e.g. of list list =[6,9]
list[0]=55
print(list[0])
print(list[1])

OUTPUT

e.g. of tuple tup=(66,99)
Tup[0]=3 \# error message will be displayed print(tup[0])
print(tup[1])
```

55

### 6. Set In Python

It is an unordered collection of unique and immutable (which cannot be modified)items.

```
e.g.
set1={11,22,33,22}
print(set1)
```

Output {33, 11, 22}

### 7. Dictionary In Python

e.g.

It is an unordered collection of items and each item consist of a key and a value.

```
dict = {'Subject': 'comp sc', 'class': '11'}
print(dict)
print ("Subject : ", dict['Subject'])
print ("class : ", dict.get('class'))

Output
{'Subject': 'comp sc', 'class': '11'}
Subject : comp sc
class : 11
```

# Type

The process of converting the value of one data type (integer, string, float, etc.) to another data type is called type conversion.

Python has two types of type conversion.

Implicit Type Conversion Explicit Type Conversion

#### **Implicit Type Conversion:**

In Implicit type conversion, Python automatically converts one data type to another data type. This process doesn't need any user involvement.

```
fium_int = 12

num_flo = 10.23

num_new = num_int + num_flo print("datatype of

num_int:",type(num_int)) print("datatype of

num_flo:",type(num_flo)) print("Value of

num_new:",num_new) print("datatype of

num_new:",type(num_new))
```

#### **OUTPUT**

('datatype of num\_int:', <type 'int'>) ('datatype of num\_flo:', <type 'float'>) ('Value of num\_new:', 22.23) ('datatype of num\_new:', <type 'float'>)

# Type conversion

#### Explicit Type Conversion:

```
In Explicit Type Conversion, users convert the data type of an object to
required data type. We use the predefined functions like int(),float(),str() etc. e.g.
num int = 12
num str = "45"
print("Data type of num int:",type(num int))
print("Data type of num str before Type Casting:",type(num str))
num str = int(num str)
print("Data type of num_str after Type Casting:",type(num_str))
num sum = num int + num str
print("Sum of num int and num str:",num sum)
print("Data type of the sum:",type(num sum))
OUTPUT
('Data type of num int:', <type 'int'>)
('Data type of num str before Type Casting:', <type 'str'>)
('Data type of num_str after Type Casting:', <type 'int'>)
('Sum of num int and num str:', 57)
('Data type of the sum:', <type 'int'>)
```
